

SHORTEST PATHS AND RELATED PROBLEMS

- Shortest path problems are pervasive in network optimization.
- A key objective of any traveler, passenger, or carrier is to move from point a to point b along a *shortest, cheapest, or most comfortable path*.
- Associating flow costs with arcs in a network, the user seeks the minimum cost path from a to b .
- In economic terms, there is a supply of one or more units at node a , a demand for these units at node b , and a link flow cost assigned to each link in the network.
- In the context of computer networks, the goal is to send packets of information from a to b with minimum delay.
- Shortest path problems are often important subproblems for more complex network problems.

TYPES OF SHORTEST PATH PROBLEMS

- For a given network G with arc costs given by the matrix $\mathbf{D} = [d(i, j)]$, there are four shortest path problems of general interest that we consider.
 - (SP1) Find the shortest path from a specific origin s to a specific destination t ;
 - (SP2) Find the shortest paths from a specific origin s to all other nodes;
 - (SP3) Find the shortest paths between all pairs of nodes;
 - (SP4) Find the second, third, and so on shortest paths.
- The distance entries $d(i, j)$ can be positive, negative, or zero provided that there is no cycle whose total cost is negative. If a negative cycle did exist, costs could be minimized by traversing it infinitely often.

SHORTEST PATHS FROM A GIVEN NODE

- An algorithm for this problem will solve the O-D path problem as well.
- Two algorithmic strategies
 - Label correcting
 - Label setting
- Label correcting methods consider all labels as temporary until the final step when they all become permanent.
- Label-setting methods designate one or more labels as permanent at each step of the procedure.

A LABEL CORRECTING ALGORITHM

Step 0. Definitions

$\ell(v)$ is the length of the current “shortest path” from node 0 to node v .

$p(v)$ is the predecessor of v in the current “shortest path” to this node.

$d(i, k)$ is the length of arc $i - k \in A$.

T is a list of nodes to be scanned.

Step 1. Initialization

$$\ell(v) = \begin{cases} 0 & \text{if } v = 0 \\ \infty & \text{otherwise.} \end{cases}$$

$$p(v) = 0 \quad \text{for all } v.$$

node 0 is the first element on list T.

A LABEL CORRECTING ALGORITHM — CONTINUED

Step 2. Basic Computation

Select the top element i from T . Scan element i . That is, for every node k such that $i - k \in A$, perform the following test:

If $\ell(i) + d(i, k) < \ell(k)$ then

$$(a) \ell(k) = \ell(i) + d(i, k)$$

$$p(k) = i, \text{ and}$$

(b) place k at bottom of T , if it is not already on the list.

Step 3. Reducing the List Size

Remove (or cross out) node i from the list. Terminate the procedure if the list T is now empty. Otherwise, go to Step 2.

COMMENTS ON THE LABEL CORRECTING APPROACH

- Step 2 implements the fundamental (DP) recursion

$$e^{k+1}(i) \leftarrow \min_j \{ e^k(j) + d(j, i) \}.$$

- The recursion states that the shortest path from the origin to node i using $k + 1$ or fewer arcs is composed of some final arc $j - i$ plus a shortest path to the predecessor j of node i using k or fewer arcs.
- The label-correcting procedure terminates with correct shortest path lengths.
- The algorithm requires at most $O(n^3)$ additions and comparisons.
- The label-setting procedure is known as Dijkstra's algorithm.

DIJKSTRA'S ALGORITHM

Step 1. Initialization

$S = \{1\}$, $R = N - S$, $\ell(1) = 0$, $\ell(j) = d(1, j)$ for $j \neq 1$, and $p(j) = 1$ for all j .

Step 2. Assign a Permanent Label

Let $\ell(j^*) = \min_{j \in R} [\ell(j)]$. Set $R \leftarrow R - \{j^*\}$ and

$S \leftarrow S + \{j^*\}$.

If $R = \emptyset$, terminate.

Step 3. Update All Labels

For all $j \in R$, let $\ell(j) = \min [\ell(j), \ell(j^*) + d(j^*, j)]$.

If $\ell(j) = \ell(j^*) + d(j^*, j)$, then $p(j) = j^*$.

Return to Step 2.

DIJKSTRA EXAMPLE

DIJKSTRA EXAMPLE

- Dijkstra's algorithm terminates with correct shortest path lengths when applied to problems with nonnegative arc lengths. The algorithm requires $O(n^2)$ additions and comparisons.

Follower Matrix

Floyd's Algorithm

Step 0. Definitions

$f_i(j, k)$ = the length of the shortest path from node j to node k using only nodes $1, \dots, i$ as intermediate nodes.

$P_i(j, k)$ = the node immediately following node j on the shortest path from node j to node k using only nodes $1, \dots, i$ as intermediate nodes.

Step 1. Initialization

$$\left. \begin{array}{l} f_0(j, k) = d(j, k) \\ P_0(j, k) = k \end{array} \right\} \text{for all } j \text{ and } k.$$

Set $i = 1$.

Floyd's Algorithm -- continued

Step 2. Check for Negative Cycles

Compute $f_{i-1}(i, j) + f_{i-1}(j, i)$ for all j . If, for some j , this sum is negative, then stop since a negative cycle has been identified.

Otherwise, go to step 3.

Step 3. Update Labels

Let $f_i(j, k) = \min [f_{i-1}(j, k), f_{i-1}(j, i) + f_{i-1}(i, k)]$ for all j and k .

For each j and k ,

$$P_i(j, k) = \begin{cases} P_{i-1}(j, k) & \text{if the first term is the minimum.} \\ P_{i-1}(j, i) & \text{otherwise.} \end{cases}$$

In case of ties, $P_i(j, k) = P_{i-1}(j, k)$.

Floyd's Algorithm -- continued

Step 4. Stopping Criterion

If $i = n$, then stop. Otherwise, increment i by 1 and return to step 2.

LONGEST (CRITICAL) PATHS IN A DIRECTED ACYCLIC GRAPH

- Assume that nodes are numbered such that all directed arcs $i-j$ have $i < j$. This can be ensured using on the order of n^2 computations in the worst case.
- A Longest Path Algorithm for Directed Acyclic Graphs

Step 1. Initialization

$$\ell(0) \leftarrow 0.$$

Step 2. Computation

$$\text{For } i = 1, 2, \dots, n, \text{ let } \ell(i) \leftarrow \max_{j: j-i \in A} \{\ell(j) + d(j, i)\}.$$

LONGEST PATH EXAMPLE

$$\ell(0) = 0$$

$$\ell(1) = 1$$

$$\ell(2) = 5$$

$$\ell(3) = \max \{4, 6\} = 6$$

$$\ell(4) = 5$$

$$\ell(5) = \max \{12, 10\} = 12$$

$$\ell(6) = \max \{13, 7\} = 13$$

$$\ell(7) = \max \{12, 17, 15\} = 17$$
